**Assessment Information**

- **Year published:** 2015
- **Date assessed:** 2015-03-31
- **Assessor(s):** BirdLife International
- **Reviewer(s):** Symes, A.
- **Compiler(s):** Ashpole, J., Burfield, I., Ieronymidou, C., Pople, R., van Kleunen A., Wheatley, H. & Wright, L.

**Assessment Rationale**

**European regional assessment:** Least Concern (LC)

**EU27 regional assessment:** Not Applicable (NA)

The range size has not been quantified, but it is not believed to approach the thresholds for Vulnerable under the population size criterion (10% in ten years or three generations, or with a specified population structure). The population size may be small, but it is not believed to approach the thresholds for Vulnerable under the population size criterion (10% in ten years or three generations, or with a specified population structure). The population trend is not known, but the population is not believed to be decreasing sufficiently rapidly to approach the thresholds under the population trend criterion (30% decline over ten years or three generations). For these reasons the species is evaluated as Least Concern in Europe.

The bird is considered vagrant in the EU27 and is assessed as Not Applicable (NA) for this region.

**Occurrence**

**Countries/Territories of Occurrence**

- **Native:**
  - Russian Federation

- **Vagrant:**
  - Denmark; Portugal; Sweden; United Kingdom

**Population**

The European population is estimated at 500-1,500 pairs, which equates to 1,000-3,000 mature individuals. The species does not occur in the EU27. For details of national estimates, see [Supplementary PDF](#).

**Trend**

In Europe the population size trend is unknown. For details of national estimates, see [Supplementary PDF](#).

**Habitats and Ecology**

In its European breeding range this species inhabits zonal dwarf birch tundra in watersheds and on mountain slopes. In the polar Urals it occurs up to 300 m Asl. It normally occurs in drier and cooler regions than those favoured by Emberiza schoeniclus. Wintering grounds are situated outside Europe, mainly in China and Korea (Hagemeijer & Blair 1997, Copete 2011). Breeding takes place in June and July. The nest is placed on the ground or low in a bush. The clutch, usually three to five eggs, is incubated by the female. The incubation period is 11 days; nestlings are fed by both parents and leave the nest after 11 days. During the breeding season the species is reported to take seeds, beetles, caterpillars and also berries (Copete 2011).

**Habitats & Altitude**

</tr>
</tbody>
</table>
The population is suspected to be stable (BirdLife International 2015). Hunting of bunting flocks for food in its Chinese wintering range may be a threat to the species. The melting of glaciers as a consequence of global warming may have adverse effects on the species's breeding habitat in the future (Copete 2011).

### Threats & Impacts

</tbody>
</table>

**Stresses**
- Species mortality
- Ecosystem conversion; Ecosystem degradation

### Conservation

#### Conservation Actions Underway

There are currently no known conservation measures for this species.

#### Conservation Actions Proposed

Study the pressures in its wintering range, in particular the impact of trapping and hunting on the whole population.
